

**Evaluation of fungicide programs for control of powdery mildew on grapevines, 2021.**

Experimental and registered fungicides were tested in various combinations for the control of powdery mildew in a 10-yrs-old ‘Chenin Blanc’ vineyard at the University of California Davis Plant Pathology Field Research Facility in Davis, CA. Rows were spaced 11 feet apart and vines 7 feet apart. Fungicide treatments were applied from mid-Apr until mid-Jul. The spray volume was gradually increased from 50 to 150 gal/A as the vines grew to ensure complete coverage. Treatments were applied to run-off using a mist blower backpack sprayer (Stihl SR 450). Treatments were performed in a complete randomized block design with four replicates of two vines each. Trial I consisted of synthetic fungicides and combinations of soft chemistry and synthetic products. Trial II consisted of soft chemistry products, including biologicals, sulfurs, nutrient applications, oils, and other materials. Spray frequencies varied from 7-day to 21-day intervals. During the spray period, vines were irrigated by drip irrigation. Sucker shoot removal and leafing were carried out on 19 Jun. Treatments were evaluated for disease incidence and severity on 20 Jul. A total of twenty-five random clusters were evaluated per replicate. Incidence was defined as the proportion of clusters in a plot showing symptoms and/or signs of powdery mildew. Severity was determined by estimating the percentage of the area of a cluster that was infected; the severity value of all clusters was then averaged to give a plot-wide estimate of disease severity. Mean incidence and severity values for each treatment were computed. Trials data were analyzed using ANOVA and means were compared using Fisher’s LSD test ( $\alpha=0.05$ ).

Temperatures were mild and dry throughout the growing season, five precipitation events of 0.02, 0.01, 0.02, 0.01, and 0.08 in. were recorded on 2, 20, and 25 Apr, 13, and 14, respectively. First signs of powdery mildew were observed in mid-May on leaves and in mid-Jun on berries. Overall, the disease pressure was low. By the time of evaluation, disease incidence and severity in the untreated control had reached 71% and 46.1%, respectively. All treatments showed a significant reduction in disease incidence and severity compared to the untreated control in both trials. In Trial I, a program consisting of synthetic fungicides and combinations of soft chemistry alternated with synthetic products completely controlled the disease, except for ReyZox 15.1 fl oz, which was the least effective treatment. The experimental materials in rotation and combination with conventional fungicides also provided satisfactory disease control. In Trial II, programs consisting of sulfur at various concentrations completely controlled the disease. Similarly, programs of sulfur in rotation with experimental fungicides also provided very good control. The least effective treatment was MinerALL 4.25 lb/100 gal. All other treatments provided at least 75% or greater control of disease severity. Phytotoxicity was observed on berries for treatment EXP1 256 fl oz + Dyne-Amic 0.125 % v/v, and on leaves for treatment PureSpray Green 1 gal (pre-bloom), then Sulfur Dry-Flowable 5 lb (after bloom) and for treatment PureSpray Foliar 22 E 0.5 gal (pre-bloom), then Sulfur Dry-Flowable 5 lb (after-bloom).

**Trial I**
